## PREFACE

In order to make our extensive series of lecture notes more readily available, we have scanned the old master copies and produced electronic versions in Portable Document Format. The quality of the images varies depending on the quality of the originals. The images have not been converted to searchable text.

## A SYSTEMATIC ANALYSIS OF DISTORTIONS IN MAP PROJECTIONS

Notes for course in Map Projections, Department of Surveying  
Engineering.

L. Hradilek and A. C. Hamilton

Preface

These notes are laid out with the intention that this booklet will serve as a notebook for the student as well as providing him with most of the material that will be presented in the lectures.

It is assumed that the student has complete mastery of the art of manipulating expressions in differential calculus, algebra and trigonometry; numerous opportunities are provided for him to practice this skill.

Acknowledgements

These notes have evolved from the lecture notes prepared by Dr. Gottfried Konecny in 1965 supplemented by material from Mathematical Cartography by F. Fiala.

Contents

Introduction

Chapter I

General expressions for distortions

Distortion in length, ellipsoid

Distortion in length, sphere

Distortion in azimuth and angle

Distortion between meridian and parallel

Distortion in area

Azimuths having minimum and maximum distortion in length

Chapter II

Simplified expressions for distortions.

Tissot's Indicatrix

Length distortion factor

Area distortion factor

Distortion in bearing

Extreme distortion in bearing and azimuth

Maximum distortion in angle

Chapter III

Analysis of distortion in cylindrical projections.

Simple cylindrical

Cylindrical equal-area

Gall's

Mercator's

#### Chapter IV

Analysis of distortion in azimuthal (zenithal) projections  
Transformation to oblique spherical coordinates from  
normal spherical coordinates  
General properties of azimuthal projections  
Gnomonic  
Stereographic  
Orthographic  
True-area  
True-meridian

#### Chapter V

Analysis of distortions in conical projections  
General equations of "genuine" conical projections  
Distortionless meridian projection on tangent cone  
Distortionless meridian projection when the pole  
is mapped as a point  
Equal-area projection  
Alber's equal-area projection with two standard  
parallels  
Conformal conical projections  
Conformal projection on one standard cone with one  
standard parallel  
Conformal conical projection with two standard  
parallels (Lambert's conformal)

#### Chapter VI

Non-Genuine Projections  
Bonne's projection

## A SYSTEMATIC ANALYSIS OF DISTORTIONS IN MAP PROJECTIONS

Notes for a course in Map Projections in  
the Department of Surveying Engineering  
University of New Brunswick

## INTRODUCTION

If we lived on a flat earth there would be no need for a course on map projections.

As it is we live on an ellipsoidal earth and there is no way that the curved surface of the earth can be portrayed on a flat sheet of paper without introducing some distortions. There are two aspects to this problem:

- (a) The mapping problem. This is the problem of representing large areas, such as continents, on a flat piece of paper. There is no perfect solution to this problem; there are only compromise solutions that have acceptable distortions.
- (b) The surveying problem. Survey measurements are made on the actual, i.e. the curved, surface of the earth; it is possible using geodetic formulae to do all computations using the curved surface as reference, however this would introduce unnecessary complications to most projects and in practice most survey projects are computed assuming some plane projection. When using a plane projection the surveyor must be aware of the distortion that occurs as a result of using the projection.

Hence in both mapping and surveying we have the problem of which projection to use and of understanding the distortions that are introduced by any projection that we do use.

There are many books written for geographers and others interested in mapping at medium and small scales where a qualitative treatment is adequate. There are also many treatises on the transformations between various projection systems; in fact, this is an integral part of the course on geometrical geodesy. The purpose of these notes is to study the inherent properties of projections quantitatively and to develop a systematic approach to the evaluation and classification of map projections.

In these notes analytical expressions for distortions in the general case are developed and applied to a representative selection of projections. It is suggested that the student refer to a descriptive text, such as Map Projections by H.S. Roblin, for illustrations and a qualitative discussion of the subject and to a textbook such as Coordinate Systems and Map Projections by D.H. Maling for more detailed treatment of the subject.

## CHAPTER I

## GENERAL EXPRESSIONS FOR DISTORTIONS

As distortions are inevitable it is necessary to deal with them quantitatively and from this to develop their significant characteristics. We will approach this problem by developing analytical expressions for various distortions starting with distortion in length. For these developments it is assumed that the curved surface - ellipsoid, or sphere, with coordinates  $\phi$  and  $\lambda$  is being mapped onto a plane with coordinates  $X$  and  $Y$  or onto a developable surface such as a cylinder or a cone. Note that a cylinder or a cone can be mapped onto a plane without any distortion.

It is assumed that there exists a functional relationship

$$X = f(\phi, \lambda) \quad : \quad Y = g(\phi, \lambda) \quad 1-1a$$

and that these are mathematically well-behaved functions having derivatives

$$dX = \frac{\partial f}{\partial \phi} d\phi + \frac{\partial f}{\partial \lambda} d\lambda \quad : \quad dY = \frac{\partial g}{\partial \phi} d\phi + \frac{\partial g}{\partial \lambda} d\lambda \quad 1-1b$$

$$\text{or} \quad dX = f_{\phi} d\phi + f_{\lambda} d\lambda \quad : \quad dY = g_{\phi} d\phi + g_{\lambda} d\lambda$$

The general expression for distortion will be developed using ellipsoidal parameters and then the simpler expression using spherical parameters will be found.

Distortion in length: ellipsoid

Fig. 1

**Earth Ellipsoid**

$M = a(1-e^2)/(1-e^2\sin^2\phi)^{3/2}$  is the radius of curvature of the meridian

$N = a/(1-e^2\sin^2\phi)^{1/2}$  is the radius of curvature of the prime vertical in which  $a$  is the length of the semi-major axis of the earth and  $e$  is the first eccentricity of the earth.

Earth sphere: This is the sphere approximating the earth; it is assumed to have radius  $R$  where  $R \approx M \approx N \approx \sqrt{MN}$ .

In these notes  $\phi$  and  $\lambda$  are used interchangeably for both the earth ellipsoid and the earth sphere. Transformations between the earth ellipsoid and the earth sphere are taken up in Geometrical Geodesy.

In Fig. 1 an elemental unit of length  $PP_1$  on the ellipsoid is mapped onto the plane as  $P'P'_1$ .

Distortion in length is defined as

$$PP_1 - P'P'_1$$

To simplify the derivation and analyses which follow we will

$$\text{set } \frac{P'P'_1}{PP_1} = m_A$$

1-2a

and call it a length distortion factor.

It follows that when  $m_A = 1$  there is zero length distortion.

**Mapping Plane**

Note that the axes have been chosen with  $X$  vertical and  $Y$  horizontal; this enables us to follow the conventional sequence i.e.  $\phi$  and  $\lambda$ ,  $X$  and  $Y$ .

From Fig. 1:

$$[p'p'_1]^2 = dY^2 + dX^2 \quad 1-3a$$

$$[PP_1]^2 = (Md\phi)^2 + (N \cos \phi d\lambda)^2 \quad 1-3b$$

$$\text{hence } m_A^2 = \frac{dX^2 + dY^2}{M^2 d\phi^2 + N^2 \cos^2 \phi d\lambda^2} \quad 1-2b$$

By substitution from 1-1b

$$m_A^2 = \frac{(f_\phi d\phi + f_\lambda d\lambda)^2 + (g_\phi d\phi + g_\lambda d\lambda)^2}{M^2 d\phi^2 + N^2 \cos^2 \phi d\lambda^2}$$

and multiplying numerator and denominator by  $\frac{1}{d\phi^2}$

$$m_A^2 = \frac{\left(\frac{f_\phi^2 + g_\phi^2}{\phi} + 2(f_\phi f_\lambda + g_\phi g_\lambda) \frac{d\lambda}{d\phi} + (f_\lambda^2 + g_\lambda^2) \left(\frac{d\lambda}{d\phi}\right)^2\right)}{M^2 + N^2 \cos^2 \phi \left(\frac{d\lambda}{d\phi}\right)^2} \quad 1-2c$$

$$\text{From fig. (1a): } \tan A = \frac{N \cos \phi d\lambda}{M d\phi}$$

$$\text{hence } \frac{d\lambda}{d\phi} = \frac{M}{N \cos \phi} \tan A \quad 1-3c$$

Exercise: By substitution from 1-3c into 1-2c show that:

$$m_A^2 = \frac{f_\phi^2 + g_\phi^2}{M^2} \cos^2 A + \frac{2(f_\phi f_\lambda + g_\phi g_\lambda)}{MN \cos \phi} \sin A \cos A + \frac{f_\lambda^2 + g_\lambda^2}{N^2 \cos^2 \phi} \sin^2 A \quad 1-2d$$

$$= m_1^2 \cos^2 A + p \sin A \cos A + m_2^2 \sin^2 A \quad 1-2e$$

$$\text{in which } m_1^2 = \frac{f_\phi^2 + g_\phi^2}{M^2}; \quad p = \frac{2(f_\phi f_\lambda + g_\phi g_\lambda)}{MN \cos \phi}; \quad m_2^2 = \frac{f_\lambda^2 + g_\lambda^2}{N^2 \cos^2 \phi} \quad 1-2f$$

Question: What condition is required for the distortion to be independent of azimuth, A?

#### Distortion in length: sphere

When considering the earth as a sphere instead of as an ellipsoid the formulas in 1-2f become

$$m_1^2 = \frac{f_\phi^2 + g_\phi^2}{R^2}; \quad p = \frac{2(f_\phi f_\lambda + g_\phi g_\lambda)}{R^2 \cos \phi}; \quad m_2^2 = \frac{f_\lambda^2 + g_\lambda^2}{R^2 \cos^2 \phi} \quad 1-2g$$

Distortion in azimuth and angle

Fig. 2

$$\text{In } \triangle P'QR: (180^\circ - A') + (180^\circ - \mu_m) + \mu_s = 180^\circ$$

$$\text{hence } 180^\circ - A' = \mu_m - \mu_s \quad 1-4a$$

$$\text{and } \tan (180^\circ - A') = \frac{\tan \mu_m - \tan \mu_s}{1 + \tan \mu_m \tan \mu_s} \quad 1-4b$$

$$\text{from } \triangle P'P'_1T: \tan \mu_s = \frac{dY}{dX}$$

$$\text{from 1-1b } \left(\frac{dY}{dX}\right)_s = \frac{g_\phi d\phi + g_\lambda d\lambda}{f_\phi d\phi + f_\lambda d\lambda} = \frac{g_\phi + g_\lambda \frac{d\lambda}{d\phi}}{f_\phi + f_\lambda \frac{d\lambda}{d\phi}} \quad 1-5a$$

Substituting for  $\frac{d\lambda}{d\phi}$  from 1-3c

$$\tan \mu_s = \frac{g_\phi N \cos \phi \cos A + g_\lambda M \sin A}{f_\phi N \cos \phi \cos A + f_\lambda M \sin A} \quad 1-5b$$

Taking an element of length along the meridian, i.e. with  $\lambda$  constant

$$\tan \mu_m = \left(\frac{dY}{dX}\right)_m = \frac{g_\phi d\phi + g_\lambda d\lambda}{f_\phi d\phi + f_\lambda d\lambda} \quad 1-6a$$

$$\text{but for } \lambda \text{ constant, } d\lambda = 0 \text{ hence } \tan \mu_m = \frac{g_\phi}{f_\phi} \quad \cdot$$

Distortion in azimuth is defined as  $A' - A$

in which  $A'$  is computed from 1-4b using  $\tan \mu_s$  from 1-5b and  $\tan \mu_m$  from 1-6a.

To get the distortion in an angle,  $\omega$ , where  $\omega = A_2 - A_1$ , we compute  $A'_1$  and  $A'_2$  from 1-4b and get the angle  $\omega' = A'_2 - A'_1$  in the mapping plane.

The angular distortion is then given by:

$$\begin{aligned}\omega' - \omega &= (A'_2 - A'_1) - (A_2 - A_1) \\ &= (A'_2 - A_2) - (A'_1 - A_1)\end{aligned}\quad 1-7$$

Special case: Distortion between meridian and parallel

Distortion in angle between the meridian and the parallel is equal to the distortion in the azimuth,  $A_p$ , where  $A_p = 90^\circ$ .

$A'_p$  is computed by substituting

$\tan \mu_p = \left(\frac{dY}{dX}\right)_\phi = \text{const}$  into 1-4b in place of  $\tan \mu_s$

from 1-1b  $\left(\frac{dY}{dX}\right)_{d\phi=0} = \frac{g_\lambda}{f_\lambda}$  1-8

$$\begin{aligned}\text{hence } \tan(180 - A'_p) &= \frac{\tan \mu_m - \tan \mu_p}{1 + \tan \mu_m \tan \mu_p} = \frac{\frac{g_\phi}{f_\phi} - \frac{g_\lambda}{f_\lambda}}{1 + \frac{g_\phi}{f_\phi} \cdot \frac{g_\lambda}{f_\lambda}} \\ &= \frac{f_\lambda g_\phi - f_\phi g_\lambda}{f_\phi f_\lambda + g_\phi g_\lambda}\end{aligned}\quad 1-9a$$

As  $\tan(180 - A'_p) = 1/\tan(A'_p - 90)$

the distortion between the meridian and the parallel is given by  $(A'_p - 90)$  and is evaluated from

$$\tan(A'_p - 90^\circ) = \frac{f_\phi f_\lambda + g_\phi g_\lambda}{f_\lambda g_\phi - f_\phi g_\lambda}\quad 1-10$$

Question: What is the value of  $A'_p - 90^\circ$  in a conformal projection?

### Distortion in area

Fig. 3

Element of area:

$$d\Sigma = ds_1 \times ds_2$$

$$d\Sigma' = ds_1' \times ds_2' \times \sin A'_p$$

Distortion in area is defined as  $d\Sigma - d\Sigma'$

For simplicity we will use  $\frac{d\Sigma'}{d\Sigma}$  and call it an area distortion factor, noting that when  $\frac{d\Sigma'}{d\Sigma} = 1$  there is zero area distortion.

$$\begin{aligned} \frac{d\Sigma'}{d\Sigma} &= \frac{ds_1' \times ds_2' \times \sin A'_p}{ds_1 \times ds_2} = \frac{ds_1'}{ds_1} \times \frac{ds_2'}{ds_1} \times \sin A'_p \\ &= m_1 \times m_2 \times \sin A'_p \end{aligned} \quad 1-11a$$

where  $m_1$  is the length distortion factor along the meridian and  $m_2$  is the length distortion factor along the parallel.

Remembering that  $\sin A'_p = \sin (180-A'_p)$  and noting that if  $\tan a = \frac{c}{d}$ ,

$$\sin a = \frac{c}{\sqrt{c^2 + d^2}}$$

then from 1-9a

$$\sin A'_p = \frac{f_\lambda g_\phi - f_\phi g_\lambda}{\sqrt{(f_\lambda g_\phi - f_\phi g_\lambda)^2 + (f_\phi f_\lambda + g_\phi g_\lambda)^2}} \quad 1-9b$$

Thus from 1-2f and 1-9b

$$\frac{d\Sigma'}{d\Sigma} = \sqrt{\frac{f_\phi^2 + g_\phi^2}{M^2}} \times \sqrt{\frac{f_\lambda^2 + g_\lambda^2}{N^2 \cos^2 \phi}} \times \frac{f_\lambda g_\phi - f_\phi g_\lambda}{\sqrt{(f_\lambda g_\phi - f_\phi g_\lambda)^2 + (f_\phi f_\lambda + g_\phi g_\lambda)^2}} \quad 1-11b$$

Exercise: Show that 
$$\frac{d\Sigma'}{d\Sigma} = \frac{|f_\lambda g_\phi - f_\phi g_\lambda|}{MN \cos \phi} \quad 1-11c$$

Question: What is the condition for a true-area projection?

Azimuths with minimum and maximum distortion in length

We apply the condition for extrema to 1-2e, namely: equate the first derivative to zero and solve

From 1-2e

$$m_A^2 = m_1^2 \cos^2 A + p \cos A \sin A + m_2^2 \sin^2 A$$

$$\frac{d(m_A^2)}{dA} = 2m_A \left( \frac{dm_A}{dA} \right), \quad \frac{dm_A}{dA} = \frac{1}{2m_A} \left( \frac{dm_A^2}{dA} \right)$$

$$\text{if } \frac{d(m_A^2)}{dA} = 0 \text{ then } \frac{dm_A}{dA} = 0 \text{ provided that } m_A \neq 0.$$

$$\frac{d(m_A^2)}{dA} = -2m_1^2 \cos A \sin A + p(-\sin^2 A + \cos^2 A) + 2m_2^2 \cos A \sin A \quad 1-12a$$

$$= -m_1^2 \sin 2A + p \cos 2A + m_2^2 \sin 2A \quad 1-12b$$

Condition for extrema:

$$(m_2^2 - m_1^2) \sin 2A_E + p \cos 2A_E = 0 \quad 1-13a$$

therefore

$$\tan 2A_E = \frac{p}{m_1^2 - m_2^2} \quad 1-13b$$

This equation can be satisfied by a value,  $A_{E1}$  and by a value,  $A_{E2}$ , equal to  $A_{E1} + 90$ . These are the azimuths of the elements of extreme distortion at point P.

To establish which of  $A_{E1}$  and  $A_{E2}$  has maximum distortion and which has minimum distortion, it is, of course, necessary to take the second derivative, substitute at the extrema; if the value is positive then it is minimum, if negative it is maximum.

## CHAPTER 11

## SIMPLIFIED EXPRESSIONS FOR DISTORTIONS

Appreciable simplifications of formulas expressing distortions may be achieved by using the directions of the extreme distortions as reference axes.

Tissot's Indicatrix

A differentially small circle on the ellipsoid is mapped as a differentially small ellipse on the plane. [This statement will not be proved here; a proof can be found in U.S.C. & G.S. Spec. Pub. No. 57 by Oscar S. Adams].

From the definition of distortion in 1-2a the magnitude of the length distortion factors in the directions of the extremes can be designated:

$$a = \frac{dX}{dx} \quad \text{and} \quad b = \frac{dY}{dy} \quad 11-1a$$

Note that this  $a$  is not to be confused with the  $a$  defined on page 2.

$$dX = a \, dx \quad dY = b \, dy \quad 11-1b$$

The equation of the small circle in Fig. 4a is

$$dx^2 + dy^2 = dr^2 \quad 11-1c$$

and after substitution from 11-1b the equation of the ellipse in Fig. 4b is

$$\frac{dX^2}{a^2} + \frac{dY^2}{b^2} = dr^2 \quad 11-1d$$

$$\text{hence} \quad \frac{dX^2}{a^2 dr^2} + \frac{dY^2}{b^2 dr^2} = 1 \quad 11-1e$$

This is the equation of Tissot's Indicatrix.

By using the axes of Tissot's Indicatrix as reference axes alternative expressions for the length distortion factor (Equation 1-2d) and the distortion in angle (Equation 1-7) can be derived.

#### Length distortion factor

From Fig. 4:

$$(P P_1)^2 = dx^2 + dy^2 = dr^2$$

$$(P' P'_1)^2 = dX^2 + dY^2 = a^2 \cos^2 \alpha dr^2 + b^2 \sin^2 \alpha dr^2$$

$$\text{as } dX = a dx \quad (\text{from 11-1b}) \text{ and } dx = dr \cos \alpha \quad (\text{from Fig. 4a})$$

$$\text{and similarly } dY = b dy, \quad dy = dr \sin \alpha$$

thus

$$\begin{aligned} m_\alpha^2 &= \left( \frac{P' P'_1}{P P_1} \right)^2 = \frac{a^2 \cos^2 \alpha dr^2 + b^2 \sin^2 \alpha dr^2}{dr^2} \\ &= a^2 \cos^2 \alpha + b^2 \sin^2 \alpha \end{aligned} \quad 11-2$$

where  $\alpha$  is the bearing measured from the x-axis, i.e. from the direction of extreme distortion,  $a$ , the azimuth of which is  $A_{E1}$ . The azimuth of the  $PP_1$  direction is  $A_{E1} + \alpha$ . This compares with

$$m_A^2 = m_1^2 \cos^2 A + m_2^2 \sin^2 A.$$

#### Area distortion factor

In Fig. 4, the area of the differentially small circle is

$$d\Sigma = \pi dr^2$$

and the area of the differentially small ellipse is

$$d\Sigma' = \pi a dr \times b dr$$

hence

$$\frac{d\Sigma'}{d\Sigma} = \frac{\pi ab dr^2}{\pi dr^2} = ab \quad 11-3$$

as compared with

$$\frac{d\Sigma'}{d\Sigma} = \frac{f_\lambda g_\phi - f_\phi g_\lambda}{MN \cos \phi} \quad (\text{in 1-11c}).$$

Distortion in bearing

From Fig. 4

$$\tan \alpha = \frac{dy}{dx} ; \quad \tan \alpha' = \frac{dY}{dX} \quad 11-4a$$

hence from 11-1b

$$\tan \alpha' = \frac{b}{a} \frac{dy}{dx} = \frac{b}{a} \tan \alpha . \quad 11-4b$$

Distortion in bearing is defined as  $\alpha' - \alpha$ .Extreme distortion in bearing and azimuthWe take the derivative of  $\alpha' - \alpha$  and equate to zero.

Thus

$$\frac{d(\alpha' - \alpha)}{d\alpha} = 0, \quad d\alpha'_E = d\alpha_E . \quad 11-4c$$

Applying this condition to the derivative of 11-4b

$$\frac{d(\tan \alpha')}{d\alpha'_E} = \frac{b}{a} \frac{d(\tan \alpha)}{d\alpha} \quad 11-4d$$

$$\frac{1}{\cos^2 \alpha'_E} = \frac{b}{a} \cdot \frac{1}{\cos^2 \alpha_E}$$

or

$$1 + \tan^2 \alpha'_E = \frac{b}{a} (1 + \tan^2 \alpha_E) . \quad 11-4e$$

Substituting from 11-4b

$$1 + \frac{b^2}{a^2} \tan^2 \alpha_E = \frac{b}{a} + \frac{b}{a} \tan^2 \alpha_E$$

$$\tan \alpha_E = \sqrt{\frac{a}{b}} . \quad 11-4f$$

But from 11-4b

$$\tan \alpha'_E = \frac{b}{a} \tan \alpha_E = \frac{b}{a} \sqrt{\frac{a}{b}} = \sqrt{\frac{b}{a}} . \quad 11-4g$$

For the computation of  $\alpha'_E - \alpha_E$ 

$$\sin (\alpha'_E - \alpha_E) = \sin \alpha'_E \cos \alpha_E - \cos \alpha'_E \sin \alpha_E . \quad 11-5a$$

$$\text{From 11-4f} \quad \sin \alpha_E = \sqrt{\frac{a}{a+b}} , \quad \cos \alpha_E = \sqrt{\frac{b}{a+b}} .$$

$$\text{From 11-4g} \quad \sin \alpha'_E = \sqrt{\frac{b}{a+b}} , \quad \cos \alpha'_E = \sqrt{\frac{a}{a+b}} .$$

$$\text{Hence} \quad \sin (\alpha'_E - \alpha_E) = \frac{b}{a+b} - \frac{a}{a+b} = \frac{b-a}{a+b} . \quad 11-5b$$

Maximum distortion in angles

The distortion  $\Delta\omega_E$  in the angle  $\omega = \alpha_2 - \alpha_1$  is estimated by its maximum value which may be two times larger than the distortion in bearing.

Thus

$$\Delta\omega_E = 2(\alpha'_E - \alpha_E) \quad 11-6a$$

and 
$$\sin\left(\frac{\Delta\omega_E}{2}\right) = \sin(\alpha'_E - \alpha_E) = \frac{b-a}{b+a} \cdot \quad 11-6b$$

Note we did not compute an extremum for angle previously. We merely found  $\omega'_2 - \omega_2 = (A'_2 - A_2) - (A'_1 - A_1)$  where  $A'_2 + A'_1$  were expressed in terms of  $\mu_m + \mu_s$ .

Note: The simplified formulas for distortions are well suited to Genuine Projections; i.e. to those in which the images of meridians and parallels remain perpendicular. In other words, those projections for which  $p = 0$ , i.e. those for which  $A_{E1} = 0$  and  $A_{E2} = 90$ . The meridians and parallels are then the directions with extreme scale factors.

## CHAPTER III

## ANALYSIS OF DISTORTION IN CYLINDRICAL PROJECTIONS

The cylindrical family of projections are illustrated and their characteristics are discussed in Roblin (pp 18-25) and in many other texts. In these notes, it will be assumed that the reader has referred to Roblin or to some similar reference for a description of the projection hence only the analytical expressions for distortion will be developed here; there will be applications of the expressions developed in Chapters I and II.

The cylinder is a useful intermediate surface between the sphere and the plane. It is called a developable surface as it may be mapped onto a plane without distortion; it is of special value in visualizing the transformation. The steps in transforming, i.e. projecting, from the ellipsoid to the plane are illustrated schematically:

FIG. 5

All transformations from the ellipsoid, whether directly to the plane or to an intermediate surface are somewhat involved mathematically. As our immediate objective is to gain an understanding of map projections in general, we will in most cases start with a spherical surface.

Simple Cylindrical

For this projection the explicit functional relationships and the derivatives corresponding to the general form in 1-1a and 1-1b are:

$$X = R\phi \qquad Y = R\lambda \qquad \text{III-1a}$$

$$\begin{aligned} f_{\phi} &= R & g_{\phi} &= 0 \\ f_{\lambda} &= 0 & g_{\lambda} &= R \end{aligned} \qquad \text{III-1b}$$

From (1-2g):

$$m_1^2 = \frac{f_{\phi}^2 + g_{\phi}^2}{R^2} \quad ; \quad p = \frac{2(f_{\phi}f_{\lambda} + g_{\phi}g_{\lambda})}{R^2 \cos \phi} \quad ; \quad m_2^2 = \frac{f_{\lambda}^2 + g_{\lambda}^2}{R^2 \cos^2 \phi}$$

$$m_1 = 1 \quad ; \quad p = 0 \quad ; \quad m_2 = \frac{1}{\cos \phi} \quad \text{III-1c}$$

What are the directions of the extrema?

$$\tan 2A_E = \frac{p}{m_1^2 - m_2^2} = 0 \quad A_{E1} = 0 \quad , \quad A_{E2} = 90^\circ$$

$$\text{therefore} \quad a = m_2 \quad b = m_1 \quad .$$

Is the projection equal-area? No

$$\text{What is the area distortion factor?} \quad a \times b = m_1 \times m_2 = \frac{1}{\cos \phi} \quad \text{III-1d}$$

Is the projection conformal? No.  $p = 0$

$$\text{but } m_1 \neq m_2 \quad .$$

Maximum distortion in angle?

$$\sin \left( \frac{\Delta \omega_E}{2} \right) = \frac{b-a}{b+a} = \frac{\sec \phi - 1}{\sec \phi + 1} \quad \text{III-1e}$$

Cylindrical equal-area

The functional relationships are:

$$X = R \sin \phi \qquad Y = R\lambda \qquad \text{III-2}$$

Exercises:

- (i) Show that  $m_1 = \cos \phi$ ,  $p = 0$ ,  $m_2 = 1/\cos \phi$  and hence that the projection is equal-area.
- (ii) Show that the maximum distortion in angle is given by

$$\sin \left( \frac{\Delta\omega}{2} \right) = \frac{\sec \phi - \cos \phi}{\sec \phi + \cos \phi}$$

Gall's projection

The functional relationships and first derivatives are:

$$x = \frac{1.7R \sin \phi}{1 + \cos \phi} \quad y = 0.7R \lambda \quad \text{III-3a}$$

$$f_{\phi} = 1.7R \left[ \frac{1}{1 + \cos \phi} \right] \quad g_{\phi} = 0 \quad \text{III-3b}$$

$$f_{\lambda} = 0 \quad g_{\lambda} = 0.7R$$

From 1-2g

$$m_1^2 = \frac{[1.7R (\frac{1}{1 + \cos \phi})]^2 + 0}{R^2}; p = 0; m_2^2 = \frac{0 + (0.7R)^2}{R^2 \cos^2 \phi}$$

$$m_1 = 1.7 (1 + \cos \phi)^{-1} \quad m_2 = \frac{0.7}{\cos \phi} \quad \text{III-3c}$$

What are the directions of the extrema?

$$\tan 2A_E = \frac{p}{m_1^2 - m_2^2} = 0; A_{E1} = 0, A_{E2} = 90^\circ$$

therefore  $a = m_2, b = m_1$

Is the projection equal-area? No

Area distortion factor?

$$a \times b = \frac{1.7}{1 + \cos \phi} \times \frac{0.7}{\cos \phi} \quad \text{III-3d}$$

Is the projection conformal? No,

$$p = 0, \text{ but } m_1 \neq m_2$$

Maximum distortion in angle?

$$\sin \left( \frac{\Delta \omega}{2} \right) = \frac{b-a}{b+a} = \frac{\frac{0.7}{\cos \phi} - 1.7 \left( \frac{1}{1 + \cos \phi} \right)}{\frac{0.7}{\cos \phi} + 1.7 \left( \frac{1}{1 + \cos \phi} \right)} \quad \text{III-3e}$$

Questions:

- (i) Under what condition is there no distortion in angle?
- (ii) How can this be reconciled with the fact that the projection is not conformal?

### Mercator's projection

The functional relationships and first derivatives

are:

$$X = R \ln \tan \left( 45^\circ + \frac{\phi}{2} \right) \quad Y = R\lambda \quad \text{III-4a}$$

$$f_\phi = \frac{R}{\cos \phi} \quad g_\phi = 0 \quad \text{III-4b}$$

$$f_\lambda = 0 \quad g_\lambda = R$$

From I-2g

$$m_1^2 = \frac{f_\phi^2 + g_\phi^2}{R^2}; \quad p = \frac{2(f_\phi f_\lambda + g_\phi g_\lambda)}{R^2 \cos \phi}; \quad m_2^2 = \frac{f_\lambda^2 + g_\lambda^2}{R^2 \cos^2 \phi}.$$

Hence

$$m_1 = \frac{1}{\cos \phi} = \sec \phi; \quad p = 0; \quad m_2 = \frac{1}{\cos \phi} = \sec \phi. \quad \text{III-4c}$$

Do the directions of extreme distortion exist?

No, because distortion is equal in all directions.

Is the projection equal-area? No.

Area distortion factor?

$$a \times b = m_1 \times m_2 = \frac{1}{\cos \phi} \times \frac{1}{\cos \phi} = \frac{1}{\cos^2 \phi}. \quad \text{III-4d}$$

Is the projection conformal? Yes

$$p = 0, \text{ and } m_1 = m_2.$$

Maximum distortion in angle? 0

$$\sin \left( \frac{\Delta \omega}{2} \right) = \frac{b-a}{b+a} = \frac{\sec \phi - \sec \phi}{\sec \phi + \sec \phi} = 0.$$

Definition: The Loxodrome or rhumb line is defined as a curve on the sphere intersecting all meridians in the same azimuth. The loxodrome is mapped as a straight line on Mercator's projection. (see Roblin p.22)

The Transverse Mercator (T.M.) projection is used mainly for bands of only a few degrees in width, the band that is 6 degrees in width is known as the Universal Transverse Mercator (U.T.M.) and is used for the National Topographic Series of maps in Canada and in many other countries. To reduce the distortion in scale a secant cylinder is generally used instead of a tangent cylinder. For a 6° zone, the cylinder is made to intersect the sphere 2° each side of the central meridian.

The Transverse Mercator projection and procedures for converting from the ellipsoid are discussed in *Coordinate Systems and Map Projections* by D. H. Maling (pp. 217-233).

## CHAPTER IV

## ANALYSIS OF DISTORTION IN AZIMUTHAL (ZENITHAL) PROJECTIONS

The azimuthal or zenithal family of projections are illustrated and their characteristics are discussed in Roblin (pp. 39-55) and in many other texts. As in Chapter III it will be assumed that the reader has referred to a descriptive text and only the analytical expressions for distortion will be discussed here. Also, as in Chapter III, discussion will be restricted to the transformation from sphere to plane. Some generality will be achieved, however, by the introduction of oblique spherical coordinates (cartographic coordinates) in place of normal spherical coordinates; by this artifice the analyses that follow will be valid regardless of the location of the tangent point.

Transformation to oblique spherical coordinates from normal spherical coordinates

Oblique spherical coordinates,  $\alpha$  and  $\delta$  are the coordinates with respect to some pole other than the north or south pole.

This is illustrated in Fig. 6 in which:

Fig. 6

N.P. is North Pole;

$O (\phi_0, \lambda_0)$  is the tangent point of an oblique projection;

$\phi, \lambda$  are the normal spherical coordinates of point P;

$\alpha, \delta$  are the oblique spherical (cartographic) coordinates of point P with respect to a pole at O.

Exercise: Prove that the two systems are related by:

$$(1) \sin \delta \sin \alpha = \cos \phi \sin \Delta \lambda$$

$$(2) \sin \delta \cos \alpha = \sin \phi \cos \phi_0 - \cos \phi \sin \phi_0 \cos \Delta \lambda \quad \text{IV-1}$$

$$(3) \cos \delta = \sin \phi \sin \phi_0 + \cos \phi \cos \phi_0 \cos \Delta \lambda$$

If necessary refer to a text on spherical trigonometry such as Schaum's notes (pp. 168-172) to verify your proof.

General properties of azimuthal projections

As azimuthal projections are symmetric about the tangent point the mathematical relationships can be conveniently expressed in polar coordinates.

Fig. 7

In Fig. 7(b)

$$X = r \cos \alpha'$$

$$Y = r \sin \alpha'$$

IV-2

$$\alpha' = \alpha$$

$$r = f(\delta)$$

IV-3

in which  $f(\delta)$  varies for different projections.

Note:

- (i) The images of cartographic meridians are straight lines, i.e.  $\alpha$  is constant.
- (ii) The images of cartographic parallels are circles, i.e.  $\delta$  is constant.
- (iii) The images of the cartographic meridians and parallels intersect perpendicularly.

Expressions for a and b (Tissot's Indices):

Fig. 8

Applying the definition of length distortion factor in 1-2a to Fig. 8

$$a = \frac{P'P'_1}{P P_1} = \frac{dr}{R d\delta} \quad \text{IV-4a}$$

$$b = \frac{P'P'_2}{P P_2} = \frac{r d\alpha'}{R \sin \delta d\alpha} \quad \text{IV-4b}$$

Exercise: Show that for all azimuthal projections  $P=0$ .

### Gnomonic Projection

The perspective centre is the centre of the sphere.

FIG. 9

$$\alpha' = \alpha$$

$$r = R \tan \delta \quad \text{IV-5a}$$

$$a = \frac{1}{R} \cdot \frac{dr}{d\delta} = \frac{1}{R} \frac{R}{\cos^2 \delta} = \frac{1}{\cos^2 \delta} \quad \text{IV-5b}$$

$$b = \frac{r d\alpha'}{R \sin \delta d\alpha} = \frac{R \tan \delta}{R \sin \delta} = \frac{1}{\cos \delta} \quad \text{IV-5c}$$

Is the projection equal-area? No.

$$ab \neq 1$$

Area distortion factor?

$$a \times b = \frac{1}{\cos^2 \delta} \cdot \frac{1}{\cos \delta} = \frac{1}{\cos^3 \delta} \quad \text{IV-5d}$$

Is the projection conformal?  $a \neq b$

Maximum distortion in angle?

$$\sin \left( \frac{\Delta\omega}{2} \right) = \frac{b-a}{b+a} = \frac{\frac{1}{\cos \delta} - \frac{1}{\cos^2 \delta}}{\frac{1}{\cos \delta} + \frac{1}{\cos^2 \delta}} = \frac{\cos \delta - 1}{\cos \delta + 1} = -\tan^2 \frac{\delta}{2} \quad \text{IV-5e}$$

Note: The most important property of the gnomonic projection is that a great circle on the sphere maps as a straight line on the projection. Such an image is called an orthodrome.

### Stereographic Projection

The perspective centre is diametrically opposite the tangent point.

Fig. 10

$$\alpha' = \alpha$$

IV-6a

$$r = 2R \tan \delta/2$$

$$a = \frac{1}{R} \cdot \frac{dr}{d\delta} = \frac{1}{R} \cdot \frac{R}{\cos^2 \delta/2} = \frac{1}{\cos^2 \delta/2}$$

IV-6b

$$b = \frac{r}{R \sin \delta} = \frac{2R \tan \delta/2}{R \sin \delta} = \frac{1}{\cos^2 \delta/2}$$

IV-6c

Similarly, as for the gnomonic projection

$$p = 0 \quad \text{and} \quad A_{E1} = 0$$

Is the projection equal-area? No.  $ab \neq 1$

Area distortion factor?

$$a \times b = \frac{1}{\cos^2 \delta/2} \times \frac{1}{\cos^2 \delta/2} = \frac{1}{\cos^4 \delta/2}$$

IV-6d

Is the projection conformal? Yes.  $a = b$

Exercise: Starting with  $X = r \cos \alpha'$  and  $Y = r \sin \alpha'$  show that

$$m_1 = \frac{1}{\cos^2 \delta/2} \quad \text{and} \quad m_2 = \frac{1}{\cos^2 \delta/2}$$

Orthographic Projection

Fig. 11

$$\alpha' = \alpha$$

$$r = R \sin \delta$$

IV-7a

$$X = r \cos \alpha' ; Y = r \sin \alpha'$$

$$\alpha' = \alpha$$

$$X = R \sin \delta \cos \alpha ; Y = R \sin \delta \sin \alpha$$

$$f_{\delta} = R \cos \delta \cos \alpha$$

$$g_{\delta} = R \cos \delta \sin \alpha$$

$$f_{\alpha} = -R \sin \delta \sin \alpha$$

$$g_{\alpha} = R \sin \delta \cos \alpha$$

$$m_1^2 = \frac{f_{\delta}^2 + g_{\delta}^2}{R^2}$$

$$m_2^2 = \frac{f_{\alpha}^2 + g_{\alpha}^2}{R^2 \sin^2 \delta}$$

$$= \frac{R^2 \cos^2 \delta \cos^2 \alpha + R^2 \cos^2 \delta \sin^2 \alpha}{R^2}$$

$$= \frac{R^2 \sin^2 \delta \sin^2 \alpha + R^2 \sin^2 \delta \cos^2 \alpha}{R^2 \sin^2 \delta}$$

$$m_1 = \cos \delta$$

$$= \frac{R^2 \sin^2 \delta (\sin^2 \alpha + \cos^2 \alpha)}{R^2 \sin^2 \delta}$$

IV-7b

$$m_2 = 1$$

By substitution it can be shown that  $p = 0$ , hence  $m_1 = a$ ,

$$m_2 = b.$$

Is the projection equal - area? No.

What is the area distortion factor?  $\cos \delta$

What is the maximum angular distortion?

It is given by:

$$\sin \left( \frac{\Delta \omega}{2} \right) = \frac{b - a}{b + a} = \frac{1 - \cos \delta}{1 + \cos \delta}$$

IV-7c

Lambert's True Area Projection

Fig. 12

$$OP = OP'$$

$$OP = 2R \sin \delta/2$$

What is the condition for a true area projection?  $a \times b = 1$

Thus if  $a = \frac{dr}{R d\delta}$  and  $b = \frac{r}{R^2 \sin^2 \delta}$

$$a \cdot b = \frac{dr}{R d\delta} \cdot \frac{r}{R^2 \sin^2 \delta} = 1$$

$$\text{i.e. } r dr = R^2 \sin^2 \delta d\delta$$

$$\int r dr = R^2 \int \sin^2 \delta d\delta$$

$$\frac{1}{2} r^2 = -R^2 \cos \delta + C$$

For  $\delta = 0$ ,  $r = 0$ , thus  $C = R^2$

$$\text{and } \frac{1}{2} r^2 = -R^2 \cos \delta + R^2 = R^2 (1 - \cos \delta)$$

$$r^2 = 2R^2 (1 - \cos \delta)$$

$$r = 2R \sqrt{\frac{1 - \cos \delta}{2}} = 2R \sin \delta/2 \quad \text{IV-8a}$$

$$OP' = OP = 2 \times (R \sin \delta/2)$$

$$x = r \cos \alpha$$

$$y = r \sin \alpha$$

$$X = 2R \sin \delta/2 \cos \alpha \quad Y = 2R \sin \delta/2 \sin \alpha$$

$$f_\delta = \frac{1}{2} 2R \cos \delta/2 \cos \alpha \quad g_\delta = \frac{1}{2} 2R \cos \delta/2 \sin \alpha$$

$$f_\alpha = -2R \sin \delta/2 \sin \alpha \quad f_\alpha = 2R \sin \delta/2 \cos \alpha$$

$$m_1^2 = \frac{R^2 \cos^2 \delta/2 \cos^2 \alpha + R^2 \cos^2 \delta/2 \sin^2 \alpha}{R^2}$$

$$m_2^2 = \frac{4R^2 \sin^2 \delta/2 \sin^2 \alpha + 4R^2 \sin^2 \delta/2 \cos^2 \alpha}{R^2 \sin^2 \delta}$$

$$m_1 = \cos \delta/2$$

$$= \frac{4R^2 \sin^2 \delta/2}{4R^2 \sin^2 \delta/2 \cos^2 \delta/2}$$

$$m_2 = \frac{1}{\cos \delta/2} \quad \text{IV-8b}$$

By substitution it can be shown that  $p = 0$

Is the projection equal area? Yes

Is the projection conformal? No

What is the maximum angular distortion?  $\frac{b-a}{b+a} = \frac{\sec \delta/2 - \cos \delta/2}{\sec \delta/2 + \cos \delta/2}$

Is it a genuine projection?

True Meridian Projection

For the projection to have zero length distortion on the meridian

a must be equal to unity. Given this condition show that:

$$1. \quad r = R\delta$$

IV-9a

$$2. \quad \text{Area distortion factor is } \delta/\sin \delta$$

$$3. \quad \text{Maximum angular distortion is } \frac{\delta - \sin \delta}{\delta + \sin \delta}$$

IV-9b

## CHAPTER V

## ANALYSIS OF DISTORTION IN CONICAL PROJECTIONS

The conical family of projections are illustrated and the characteristics of some representative examples are presented in Roblin (pp. 26-33) and in many other texts. As for the previous chapters, it will be assumed that the reader has referred to a descriptive text and only the analytical expressions for distortions will be discussed here.

Also, as for zenithal projections the cartographic coordinates  $(\delta, \alpha)$  will be used.

For "Genuine" conical projections the images of cartographic meridians are straight lines which are convergent to one point and the images of cartographic parallels ( $\delta = \text{const}$ ) are concentric circles. By virtue of this similarity the Tissot's indices,  $a$  and  $b$ , are the same as for zenithal projections (see Fig. 8 and equations IV-4a and b) in which

$$\text{if } \frac{d\alpha'}{d\alpha} = n \quad ; \quad b = \frac{rn}{R \sin \delta}$$

Fig. 14

General equations of "genuine" conical projections

$$\alpha' = n \alpha \quad 0 < n \leq 1 \quad V-1$$

$$r = f(\delta)$$

$\alpha'_M$  is defined as the value of  $\alpha'$  for  $\alpha = 2\pi$

Thus  $\alpha' : \alpha = \alpha'_M : 2\pi$

$$\alpha' = \frac{\alpha'_M}{2\pi} \cdot \alpha, \text{ hence } n = \frac{\alpha'_M}{2\pi} \quad V-2$$

For one standard parallel:

from fig. 14(b)  $\alpha'_M = \frac{2\pi R \sin \delta_o}{r_o}$

$$\therefore \alpha' = \frac{2\pi R \sin \delta_o}{2\pi r_o} \cdot \alpha, \text{ hence } \underline{n = \frac{R \sin \delta_o}{r_o}} \quad V-3$$

For tangent cone:

$$r_o = R \tan \delta_o$$

$$\alpha' = \frac{R \sin \delta_o}{R \tan \delta_o} \cdot \alpha = \cos \delta_o \cdot \alpha, \text{ hence } \underline{n = \cos \delta_o} \quad V-4$$

Distortionless meridian projection on tangent cone

Fig. 15

Condition for distortionless meridians:

$$TP = TP' : TP = R (\delta_o - \delta)$$

$$r = r_o - TP' = r_o - TP$$

$$r = r_o - R(\delta_o - \delta)$$

Equations of the projection:

$$\alpha' = \cos \delta_o \alpha$$

$$r = r_o - R(\delta_o - \delta) \quad V-5$$

where  $r_o = R \tan \delta_o$

For the cartographic pole,  $\delta=0$ , and  $r = r_o - R\delta_o$   
(i.e. The pole maps as a circle)

Exercises: (1) Show that  $a = 1$ , i.e. that the meridian is distortionless.

(2) Show that  $b = \frac{\sin \delta_o + (\delta - \delta_o) \cos \delta_o}{\sin \delta}$

Distortionless meridian projection when the pole is mapped as a point

Fig. 16

Condition:  $r_o = TV = TO$

where  $TO = R\delta_o$

$$r_o = R\delta_o$$

$$\alpha' : \alpha = \alpha'_M : 2\pi$$

$$\alpha' = \frac{\alpha'_M}{2\pi} \cdot \alpha$$

$$\text{But } \alpha'_M = \frac{2\pi R \sin \delta_o}{r_o}$$

$$\alpha' = \frac{2\pi R \sin \delta_o}{R \delta_o \cdot 2\pi}$$

$$\text{Hence } n = \frac{\sin \delta_o}{\delta_o} \quad V-6$$

Equations of the projection:

$$\alpha' = \frac{\sin \delta_o}{\delta_o} \alpha$$

$$r = r_o - R(\delta_o - \delta) = r_o - R\delta_o + R\delta = R\delta \quad V-7$$

To find Tissot's Indicatrices:

$$a = \frac{dr}{Rd\delta} = \frac{Rd\delta}{Rd\delta} = 1$$

$$b = \frac{r}{R \sin \delta} \cdot \frac{d\alpha'}{d\alpha} = \frac{R\delta}{R \sin \delta} \cdot \frac{\sin \delta_o}{\delta_o} = \frac{\delta \sin \delta_o}{\delta_o \sin \delta}$$

Is this projection equal-area? No

What is the area distortion factor?

What is the maximum angular distortion?

Equal-area projection

Condition:  $a.b = 1$

$$\text{i.e. } \frac{dr}{R d\delta} \cdot \frac{r}{R \sin \delta} \cdot \frac{d\alpha'}{d\alpha} = 1$$

But we define  $\alpha' = n\alpha$

hence  $d\alpha' = n d\alpha$

$$\text{Thus } \frac{n r dr}{R^2 \sin \delta d\delta} = 1$$

Integration gives

$$n \int r dr = R^2 \int \sin \delta d\delta$$

$$\text{and } \frac{1}{2} n r^2 = -R^2 \cos \delta + C R^2$$

in which  $C R^2$  is an arbitrary constant,

$$\text{which gives } r = R \sqrt{\frac{2}{n}} \sqrt{C - \cos \delta}$$

V-8

and along with  $\alpha' = n \alpha$  defines any equal-area conical projection  
 $n$ , and  $c$  are constants which may be derived to satisfy any two  
 conditions of our choice

e.g. (1) Pole to be mapped as a point

(2) Parallel  $\delta_0$  mapped without distortion (one std. parallel)

$$\text{From (1) when } \delta = 0, r = 0 \quad 0 = R \sqrt{\frac{2}{n}} \sqrt{C - 1}$$

$$\text{hence } C = 1$$

$$\text{From (2) and V-3 for one std. parallel } n = \frac{R \sin \delta_0}{r_0}$$

Thus the equations for the equal-area projection with one  
 standard parallel and in which the pole is mapped as a point are:

$$r = R \sqrt{\frac{2}{n}} \sqrt{1 - \cos \delta}$$

$$\alpha' = n\alpha = \frac{R \sin \delta_0}{r_0} \alpha$$

V-9

Exercise: Show that  $a.b = 1$

Alber's equal-area projection with two standard parallels

Fig. 17

Given  $R$ ,  $\delta_1$  and  $\delta_2$

$$\alpha'_M = \frac{2\pi R \sin \delta_1}{r_1}$$

From V-2  $\frac{\alpha'_M}{2\pi} = n$

For one standard parallel

$$R \sin \delta_1 = n r_1$$

Similarly, for the second standard parallel

$$R \sin \delta_2 = n r_2$$

Thus, we have two conditions for finding the unknown

constants  $n$  and  $c$ :

$$R \sin \delta_1 = n R \sqrt{\frac{2}{n} C - \cos \delta_1}$$

$$R \sin \delta_2 = n R \sqrt{\frac{2}{n} C - \cos \delta_2}$$

Squaring:

$$\sin^2 \delta_1 = 2n (C - \cos \delta_1) \quad V-10a$$

$$\sin^2 \delta_2 = 2n (C - \cos \delta_2) \quad V-10b$$

$$\therefore \frac{\sin^2 \delta_1}{\sin^2 \delta_2} = \frac{C - \cos \delta_1}{C - \cos \delta_2} \quad \text{i.e.} \quad \frac{1 - \cos^2 \delta_1}{1 - \cos^2 \delta_2} = \frac{C - \cos \delta_1}{C - \cos \delta_2}$$

By cross multiplication:

$$C - C \cos^2 \delta_1 - \cos \delta_2 + \cos^2 \delta_1 \cos \delta_2 =$$

$$C - C \cos^2 \delta_2 - \cos \delta_1 + \cos \delta_1 \cos^2 \delta_2$$

$$C(\cos^2 \delta_2 - \cos^2 \delta_1) = \cos \delta_2 - \cos \delta_1 + \cos \delta_1 \cos^2 \delta_2 - \cos^2 \delta_1 \cos \delta_2$$

$$" = " + \cos \delta_1 \cos \delta_2 (\cos \delta_2 - \cos \delta_1)$$

$$C = \frac{(\cos \delta_2 - \cos \delta_1) (1 + \cos \delta_1 \cos \delta_2)}{(\cos \delta_2 - \cos \delta_1) (\cos \delta_2 + \cos \delta_1)} \quad V-11$$

To get  $n$ , subtract V-10b from V-10a:

$$1 - \cos^2 \delta_1 = 2n C - 2n \cos \delta_1$$

$$1 - \cos^2 \delta_2 = 2n C - 2n \cos \delta_2$$

$$\cos^2 \delta_2 - \cos^2 \delta_1 = 2n (\cos \delta_2 - \cos \delta_1)$$

$$n = \frac{\cos \delta_2 + \cos \delta_1}{2} \quad V-12$$

$$\text{Hence:} \quad \alpha' = \frac{\cos \delta_2 + \cos \delta_1}{2} \cdot \alpha \quad V-13$$

$$r = \frac{2R}{\sqrt{\cos \delta_1 + \cos \delta_2}} \sqrt{\frac{1 + \cos \delta_1 \cos \delta_2}{\cos \delta_1 + \cos \delta_2} - \cos \delta}$$

To find a and b:  $a = \frac{dr}{R d\delta}$  ;  $b = \frac{r}{R \sin \delta} \cdot \frac{d\alpha'}{d\alpha}$

$$r = R \sqrt{\frac{2}{n}} \sqrt{C - \cos \delta}$$

$$dr = R \frac{1}{2} \sqrt{\frac{2}{n}} \cdot \frac{\sin \delta d\delta}{\sqrt{C - \cos \delta}}$$

$$a = \frac{R}{\sqrt{2n}} \cdot \frac{\sin \delta d\delta}{\sqrt{C - \cos \delta}} \cdot \frac{1}{R d\delta} = \frac{1}{\sqrt{2n}} \cdot \frac{\sin \delta}{\sqrt{C - \cos \delta}}$$

$$b = \frac{R \sqrt{\frac{2}{n}} \sqrt{C - \cos \delta}}{R \sin \delta} \cdot \frac{\cos \delta_2 + \cos \delta_1}{2}$$

$$\text{but } \frac{\cos \delta_2 + \cos \delta_1}{2} = n$$

$$b = \frac{\sqrt{2n} \sqrt{C - \cos \delta}}{\sin \delta}$$

$$a \cdot b = 1$$

To show that the parallel defined by  $\delta_1$  is standard (i.e.  $b = 1$ )

$$\begin{aligned} b &= \frac{\sqrt{2n} \sqrt{C - \cos \delta}}{\sin \delta} \cdot \frac{\sqrt{2n} \sqrt{C - \cos \delta_1}}{\sin \delta_1} \\ &= \sqrt{2} \cdot \frac{\sqrt{\frac{\cos \delta_2 + \cos \delta_1}{2}}}{\sin \delta_1} \cdot \frac{\sqrt{\frac{1 + \cos \delta_1 \cos \delta_2}{\cos \delta_1 + \cos \delta_2} - \cos \delta_1}}{\sin \delta_1} \\ &= \frac{\sqrt{\cos \delta_2 + \cos \delta_1} \cdot \sqrt{\frac{1 + \cos \delta_1 \cos \delta_2 - \cos \delta_1 (\cos \delta_1 + \cos \delta_2)}{\cos \delta_1 + \cos \delta_2}}}{\sin \delta_1} \\ &= \frac{\sqrt{1 + \cos \delta_1 (\cos \delta_2 - \cos \delta_1 - \cos \delta_2)}}{\sin \delta_1} = \frac{\sqrt{1 - \cos^2 \delta_1}}{\sin \delta_1} = 1 \end{aligned}$$

Note: In this discussion of Alber's projection it was assumed that  $\delta_1$  and  $\delta_2$  were given. It may be that we want to choose  $\delta_1$  and  $\delta_2$  to satisfy some condition, e.g. the condition that the angular distortion at the upper and lower ends of the map should be equal to each other and also equal to the angular distortion in the central part of the map.

If  $\delta'$  is the cartographic latitude of the top and  $\delta''$  the cartographic latitude of the bottom of the map then the condition specified above will be satisfied when

$$\begin{aligned} \cos \frac{\delta_2 - \delta_1}{2} &= \sqrt{\cos \frac{\delta'' - \delta'}{2}} \\ \cos \frac{\delta_2 + \delta_1}{2} &= \frac{\cos \frac{\delta'' + \delta'}{2}}{\sqrt{\cos \frac{\delta'' - \delta'}{2}}} \end{aligned}$$

The proof for this can be found in T.R. No. 5, D.S.E., Map Projections by G. Konecny, pp. 29-34.

### Conformal conical projections

For conformality  $a = b$

$$a = \frac{dr}{R d\delta} \quad , \quad b = \frac{n r}{R \sin \delta}$$

$$\text{Hence } \frac{dr}{r} = n \frac{d\delta}{\sin \delta}$$

$$\int \frac{dr}{r} = \ln r + c$$

$$\int \frac{d\delta}{\sin \delta} = \int \frac{\sin^2 \delta/2 + \cos^2 \delta/2}{\sin \delta/2 \cos \delta/2} d\delta/2$$

$$= \int \frac{\sin \delta/2}{\cos \delta/2} d\delta/2 + \int \frac{\cos \delta/2}{\sin \delta/2} d\delta/2$$

$$= -\ln \cos \delta/2 + \ln \sin \delta/2 + c = \ln \tan \delta/2 + c$$

$$\ln r = n \cdot \ln \tan \delta/2 + \ln c$$

$$\left. \begin{aligned} r &= c (\tan \delta/2)^n \\ \text{and } \alpha' &= n \alpha \end{aligned} \right\} \begin{array}{l} \text{General equations} \\ \text{of conformal} \\ \text{conical projections.} \end{array}$$

V-14

### Conformal projection on tangent cone

#### with one standard parallel

Fig. 18

From V-4 for tangent cone:

$$n = \cos \delta_0 \text{ and } r_0 = R \tan \delta_0$$

For  $r = r_0$

$$R \tan \delta_0 = c (\tan \delta_0/2)^{\cos \delta_0}$$

$$\text{i.e. } c = \frac{R \tan \delta_0}{(\tan \delta_0/2)^{\cos \delta_0}}, \text{ and}$$

$$r = \frac{R \tan \delta_0}{(\tan \delta_0/2)^{\cos \delta_0}} (\tan \delta/2)^{\cos \delta_0}$$

$$\alpha' = \cos \delta_0 \alpha \quad \text{V-15}$$

For the pole:

$$\lim_{\delta \rightarrow 0} r = 0$$

$\therefore$  the pole maps as a point.

Exercise:

Show that 
$$a = \frac{dr}{R d\delta} = \frac{\sin \delta_0}{\sin \delta} \cdot \frac{(\tan \delta/2)^{\cos \delta_0}}{(\tan \delta_0/2)^{\cos \delta_0}}$$

$$b = \frac{nr}{R \sin \delta} = \frac{\sin \delta_0}{\sin \delta} \cdot \frac{(\tan \delta/2)^{\cos \delta_0}}{(\tan \delta_0/2)^{\cos \delta_0}}$$

Conformal conical projection  
with two standard parallels  
(Lambert's conformal)

Fig. 19

Condition for standard parallels:

Sphere

Plane

$$2\pi R \sin \delta_1 = r_1 \alpha'_M = r_1 2\pi n$$

$$2\pi R \sin \delta_2 = r_2 \alpha'_M = r_2 2\pi n$$

But for conformal projection

$$r = c (\tan \delta/2)^n$$

$$\text{For } r = r_1: 2\pi R \sin \delta_1 = c(\tan \delta_{1/2})^n \cdot 2\pi n$$

V-16

$$\text{For } r = r_2: 2\pi R \sin \delta_2 = c(\tan \delta_{2/2})^n \cdot 2\pi n$$

$$\text{Dividing: } \frac{\sin \delta_1}{\sin \delta_2} = \frac{(\tan \delta_{1/2})^n}{(\tan \delta_{2/2})^n}$$

$$n = \frac{\ln \sin \delta_1 - \ln \sin \delta_2}{\ln \tan \delta_{1/2} - \ln \tan \delta_{2/2}}$$

V-17

$$\text{and from V-16 } c = \frac{R \sin \delta_1}{n(\tan \delta_{1/2})^n} = \frac{R \sin \delta_2}{n(\tan \delta_{2/2})^n}$$

V-18

By using a series of these the world, except for polar regions, can be mapped conformally.

CHAPTER VI  
NON-GENUINE PROJECTIONS

In non-genuine projections:

(1) The images of meridians and parallels do not intersect perpendicularly.

(2) The meridians and parallels are not the directions of extreme distortion. Thus the simplified expressions (Ch. II) for computing distortions cannot be used; it is necessary to use the general expressions developed in Ch. I.

There is no limit to the number of non-genuine projections that one can devise. Bearing in mind that these projections are not conformal their usefulness to surveyors is limited. Nevertheless countless non-genuine projections have been developed and a few have been found to be useful; Bonne's projection is one of these. It is analyzed here to illustrate the flexibility and the problems that arise in the use of a non-genuine projection. It can be classified as a pseudo-conical projection.

Fig. 20

Bonne's Projection

As illustrated and described in Roblin, p. 31 in this projection the sphere is mapped onto the tangent cone and

- (1) The images of the parallels are concentric circles without distortion in length.
- (2) The mid-meridian is standard.

For simplicity we will use geographic rather than cartographic coordinates.

$$\text{For the tangent cone} \quad r_0 = R \cot \phi_0 \quad \text{VI-1}$$

$$\text{For standard parallels (i.e. all of them)} \quad R \lambda \cos \phi = r \alpha' \quad \text{VI-2}$$

$$\text{For the standard mid-meridian} \quad r = r_0 + R(\phi_0 - \phi) \quad \text{VI-3}$$

Thus the equations of Bonne's projection are:

$$r = r_0 + R(\phi_0 - \phi) ; \quad \alpha' = \frac{R \cos \phi}{r} \lambda$$

$$\text{i.e.} \quad X = r_0 - r \cos \alpha' ; \quad Y = r \sin \alpha' \quad \text{VI-4}$$

$$\frac{\partial X}{\partial r} = -\cos \alpha' \quad \frac{\partial Y}{\partial r} = \sin \alpha'$$

$$\frac{\partial X}{\partial \alpha'} = r \sin \alpha' \quad \frac{\partial Y}{\partial \alpha'} = r \cos \alpha' \quad \text{VI-5}$$

$$\frac{\partial r}{\partial \phi} = -R \quad \frac{\partial \alpha'}{\partial \phi} = \frac{(r_0 + R\phi_0 - R\phi)(-\sin \phi) - \cos \phi(-R)}{(r_0 + R\phi_0 - R\phi)^2} \cdot R\lambda$$

$$\frac{\partial r}{\partial \lambda} = 0 \quad = [-r \sin \phi + R \cos \phi] \frac{R\lambda}{r^2}$$

$$\frac{d\alpha'}{d\lambda} = \frac{R \cos \phi}{r}$$

$$\begin{aligned} f_\phi &= \frac{\partial X}{\partial r} \cdot \frac{\partial r}{\partial \phi} + \frac{\partial X}{\partial \alpha'} \cdot \frac{\partial \alpha'}{\partial \phi} = -\cos \alpha'(-R) + r \sin \alpha' [R \cos \phi - r \sin \phi] \frac{R\lambda}{r^2} \\ &= R[\cos \alpha' - \lambda \sin \alpha'(\sin \phi - \frac{R \cos \phi}{r})] \end{aligned}$$

$$f_\lambda = \frac{\partial X}{\partial r} \cdot \frac{\partial r}{\partial \lambda} + \frac{\partial X}{\partial \alpha'} \cdot \frac{\partial \alpha'}{\partial \lambda} = 0 + r \sin \alpha' \times \frac{R \cos \phi}{r} = R \sin \alpha' \cos \phi$$

$$\begin{aligned} g_\phi &= \frac{\partial Y}{\partial r} \cdot \frac{\partial r}{\partial \phi} + \frac{\partial Y}{\partial \alpha'} \cdot \frac{\partial \alpha'}{\partial \phi} = \sin \alpha'(-R) + r \cos \alpha' [-r \sin \phi + R \cos \phi] \frac{R\lambda}{r^2} \\ &= -R[\sin \alpha' + \lambda \cos \alpha'(\sin \phi - \frac{R \cos \phi}{r})] \end{aligned}$$

$$g_\lambda = \frac{\partial Y}{\partial r} \cdot \frac{\partial r}{\partial \lambda} + \frac{\partial Y}{\partial \alpha'} \cdot \frac{\partial \alpha'}{\partial \lambda} = 0 + r \cos \alpha' \times \frac{R \cos \phi}{r} = R \cos \alpha' \cos \phi$$

VI-6

$$m_1 = \sqrt{\frac{f_\phi^2 + g_\phi^2}{R^2}} = \sqrt{1 + \lambda^2 \left( \sin \phi - \frac{R \cos \phi}{r} \right)^2}$$

$$p = 2 \frac{f_\phi f_\lambda + g_\phi g_\lambda}{R^2 \sin \phi} = 2\lambda \left( \frac{R \cos \phi}{r} - \sin \phi \right) \quad \text{VI-7}$$

$$m_2 = \sqrt{\frac{f_\lambda^2 + g_\lambda^2}{R^2 \cos^2 \phi}} = \sqrt{\frac{R^2 \cos^2 \phi (\sin^2 \alpha' + \cos^2 \alpha')}{R^2 \cos^2 \phi}} = 1$$

Hence we get

$$m_A^2 = \left[ 1 + \lambda^2 \left( \sin \phi - \frac{R \cos \phi}{r} \right)^2 \right] \cos^2 A + \sin^2 A - 2\lambda \left( \sin \phi - \frac{R \cos \phi}{r} \right) \sin A \cos A$$

$$\text{Let } q = \lambda \left( \sin \phi - \frac{R \cos \phi}{r} \right)$$

$$m_A^2 = (\cos^2 A + \sin^2 A) + q^2 \cos^2 A - 2q \sin A \cos A$$

$$\frac{dm_A^2}{dA} = -2q^2 \cos A \sin A - 2q(\cos^2 A - \sin^2 A)$$

$$= -q^2 \sin 2A_E - 2q \cos 2A_E = 0$$

$$\tan 2A_E = -2/q = \frac{-2}{\lambda \left( \sin \phi - \frac{R \cos \phi}{r} \right)}$$

which yields

$$A_{E1} \text{ and } A_{E1} + 90^\circ$$

Exercise: Show that Bonne's projection is an equal-area projection,

i.e. show that:

$$|f_\lambda g_\phi - f_\phi g_\lambda| = R^2 \cos \phi$$
